INTRODUCTION

Due to growing concern about future groundwater supplies, the Salt River Valley Cooperative Study was initiated, in 1978, as a cooperative effort between the Department of Water Resources (DWR) (formerly the Arizona Water Commission), Municipal Water Users Association (MWUA-Phoenix, Tempe, Scottsdale, Mesa, and Glendale), Salt River Project (SRP), and several other agencies. A cooperative study allowed the agencies involved to minimize duplication of effort and maximize the use of existing data on the groundwater resource.

The purpose of the study was twofold, (1) to establish a groundwater data base, and (2) to develop a computerized groundwater model of the valley that could be used by the participating agencies in their groundwater planning and management programs.

CHAPTER I DESCRIPTION OF THE MODELING EFFORT

The study consisted of two phases. Phase I included the initial data collection and compilation efforts. It culminated in the production of the "Interim Report: Groundwater Resources Study, Executive Summary" (June, 1979). Included in the report was a discussion of amounts of groundwater in storage, aquifer characteristics, well production characteristics, water quality and data needs in the Salt River Valley (SRV). The report also described the groundwater data base which resulted from the data collection efforts. The data base consists of parameters used as model input and include water levels, specific yield, transmissivity, pumpage, and recharge. Although it was initially designed to include data for the years 1957-1977, due to information deficiencies, the data base is complete only for the years 1964-1977.

Phase II of the study, started in July 1979 and completed in June 1980, was designed to use the data collected to develop and calibrate a groundwater model of the Salt River

Valley aquifer system. Due to difficulties with the available data, the groundwater model was calibrated only for the period 1972-1977.

The purpose of this report is to provide documentation on the technical aspects of the computer model, including discussions on input parameters, estimation techniques, and results of calibration. The data collection methods and the techniques used for data estimation are described in detail. Changes in values of input parameters, which were required to calibrate the model, are also discussed.

THE MODEL

The model used for the Salt River Valley (SRV) Cooperative Study is a modified version of the U.S. Geological Survey (USGS) three-dimensional groundwater flow model. The model uses the strongly implicit procedure (SIP) iterative numerical technique to solve the set of simultaneous finite difference equations defining groundwater flow described by Trescott, 1975 (Ref. No. 42). This part of the model, known as the SOLVE Subroutine in the program documentation, was used exactly as published. Modifications to the program, involving mainly data input and output, were made to make the model more efficient for the computer system used by the DWR and do not change the solution technique.

The model is designed to solve the set of finite difference equations approximating three-dimensional groundwater flow. It has the capability, through input options, of being used as a two-dimensional model, which is how it was used in the SRV Cooperative Study. This option was chosen because of the lack of data on aquifer parameter variation with depth and lack of an adequate subsurface geologic model of the study area.

THE MODELING PROCESS

The standard approach in modeling of groundwater flow involves building a mathematical model of a basin and calibrating the model by attempting to simulate historical groundwater conditions. Calibration is a trial and error process of adjusting the model input data as reasonable and necessary to best simulate observed groundwater level fluctuations. The values arrived at for the various parameters in the final calibration are acceptable only if they are reasonable measures of the prevailing geologic and hydrologic conditions.

Calibration of the SRV model was attempted only for the period 1964-1977. Data were not sufficient to model the SRV prior to extensive groundwater development (steady state condition) or throughout the history of development. Calibration started with the earliest period of record for which reliable pumpage data existed - approximately 1964 - when the first detailed pumpage estimates were available for the SRV.

GENERAL MODEL INPUT AND RESULTS

Modeling the historical response of a groundwater system requires information on groundwater elevations, aquifer transmissivities, recharge, pumpage and other types of discharge and aquifer storage properties (specific yields or storage coefficients). In addition to the physical parameters used in the solution of the flow equations, the model area must be subdivided into discrete units, time intervals must be selected, and physical boundaries of the system must be defined.

In a finite-difference model, the general geographic distribution of the input parameters is defined by an orthogonal grid system and described by a unique set of coordinates. The system used to model the SRV was a 79 by 48 grid with each individual grid member (node) representing one

square mile. This grid is similar to the township-range grid, and the two grid systems match within one-half mile throughout the model. For descriptive purposes, it can be assumed that they coincide.

The time intervals used for simulation periods were predominantly controlled by the availability of pumpage estimates. The best combination of information on these two parameters provided three periods in which data were suitable for simulation. The three consecutive periods are 1964-1969, 1969-1972, and 1972-1977.

Model boundary conditions were used to establish the physical limits of the groundwater system and to simulate the conditions of flow where it existed. Two boundary conditions were modeled in the SRV--no flow and constant flow. Mountain fronts were considered no flow boundaries because the rock-types the mountains are comprised of are relatively impermeable and very little recharge occurs. In areas where the SRV is connected to other basins, groundwater flow across arbitrary boundaries was treated as constant flow. Values of inflow and outflow, as appropriate, were estimated on the basis of flow net analyses for these boundaries.

CHAPTER II SPECIFIC MODEL INPUT PARAMETERS

The values for parameters described herein are first approximations, based on analyses of the basic data gathered during Phase I of the study. Every effort was made to gather actual measurements or observations for each of the input parameters; when this was not possible, values were estimated. The following parameters are described in detail: water-level elevation, specific yield, transmissivity, pumpage, and recharge. The data input file which was established as a result of the data collection efforts, and data sources are described. Due to the extensive nature of the recharge file, it is described in detail according to source type.

WATER-LEVEL ELEVATIONS

A parameter necessary for groundwater modeling efforts is water-level elevation. Water-level elevations are needed for each active node in the system. Active nodes are those involved in the finite-difference approximation equations. Water-level elevation data are necessary for the beginning of each simulation period for each active node in the model, and water-level elevations for the end of each period must be available for comparison to the water-level elevations calculated by the model.

Data Sources

Water-level data are available for most years as far back as the early 1900's. However, total coverage of the study area for any single year is available for only a few years between 1957 and 1977.

In the last 25 years, major programs have been developed to determine static water levels in wells during the nonirrigation (winter) season. However, these programs have been sporadic. Water-level measurements for the entire SRV made during the early 1960's roughly coincide with the first detailed estimates of pumpage for the entire SRV. Because of the lack of data for the entire model area prior to this time, data collection efforts were concentrated on the period from the early sixties to 1978. Water-level elevation contour maps for 1964, 1969, 1972 and 1976-1977 are available from previous work. The 1964 and 1969 maps were produced by the USGS. The 1972 map was produced by the Bureau of Reclamation as part of their study of the Central Arizona Project (CAP) service area. The USGS, in 1976, initiated an intensive basic data collection effort of the entire SRV which was published in two reports by Laney, Ross and Littin, 1978 (Ref. No. 25) and Ross, 1977 (Ref. No. 38). The water-level elevation contour maps from these reports (See Plate No. 1) were modified for use in the model study.

Data Input

Water-level elevation values for each node were determined from contour maps, and, where available, values were determined from field measurements. In nodes where more than one well had been measured, an average value was used. Nodes without measurements were assigned values interpolated from the contour maps. Values from the node map have been included in a computerized water-level file for use as beginning and/or ending water levels for each simulation period.

SPECIFIC YIELD

Specific yield is a measure of an aquifer's storage capability. It is an important parameter in groundwater modeling because it is the controlling factor in the amount of water level change that occurs as a result of changes in storage in a given node. There are only two sources of water in modeling, water released from storage and water derived from recharge. In the SRV, recharge is less than half of the total water withdrawn; therefore, storage release is the predominant source of water. In as much as storage release is the predominant source of water to the model, and water level changes are required for water to be released from storage, the model is very sensitive to withdrawal from storage. Minor changes in specific yield may cause significant water level changes. Specific yields have been estimated for each of the active nodes in the model grid.

Data Sources

Input values for specific yield in groundwater modeling studies are always based on estimates. Actual measurements of specific yield are difficult to obtain. Estimates of specific yield come from (1) aquifer tests, (2) volumetric changes in

storage analyzed using the simple equation: volume of dewatered sediment divided into the volumetric difference between water removed and water returned, and (3) comparisons of aquifer material types to experimentally obtained specific yield values of similar aquifer materials.

The SRV model study used a computerized version of method number three, the DWR Aquifer Parameter Program. This method was used because of the lack of long-term aquifer testing information, and volumetric determinations of specific yield are complicated by the lack of reliable information on recharge. The DWR Aquifer Parameter Program utilizes the driller's description of aquifer material to assign an empirically determined specific yield value (Davis and others, 1959, Ref. No. 15). A weighted average specific yield value for each driller log was calculated from the individual specific yield values assigned to each material type listed in the log. The specific yield values for each well were plotted, and zones of very low (.01 - .05), low (.06 - .10), moderate (.1 - .20), and high (.20 - .25) specific yield were delineated. Specific yield values for each node were assigned according to the specific yield zone map. Driller logs for this effort were collected from the USGS well files, DWR well files, and irrigation district's, cities', and private water companies' files.

Data Estimates

Of the several input parameters used in the modeling process, specific yield is one of the least reliable because of the difficulty in obtaining measured values. Therefore, it is one of the first parameters to be evaluated and changed in the calibration process. The range of values used in the modeling effort is considered to be reasonable when compared to values estimated by other researchers. However, site specific values can have significant errors.

Error may be introduced into an estimate of specific yield from inaccuracies in the driller's identification of the aquifer material types. There are enough logs, however, so that general lithologic patterns can be seen and logs that misrepresent the lithology of any area appear as anomalies when presented in map form. Anomalous specific yield values are readily apparent and not used in the analyses.

Error is also introduced in specific yield values for each driller log material type because the assigned values are averages. For example, clay is assigned an average specific yield of 3 percent whereas different types of clay may actually range from 1 percent to 5 percent. This error is considered minor and generally does not affect the relative values of low to moderate specific yield.

A specific yield zone map was generated from approximately 2,000 driller logs in the SRV. A zone map was used instead of contoured data because contours do not adequately reflect the random variation in specific yield of the interbedded aquifer materials of basin fill sediments. Aquifer material changes occur over distances of a few feet and are not adequately represented by contours on a map scale of one-half inch to the mile. Contours also imply variations in specific yield are separated by intermediate values, which is not always the case. The zone map represents areas of similar specific yield, not gradational changes from high to low or vice-versa.

Although the specific yield values used are not absolutely correct, the relative distribution of low, moderate, and high specific yield values are good. The good representation of the distribution of relative values provided by the DWR program is one reason for choosing this method of parameter estimation.

Data Input

The specific yield value required for each node in the model is that which is representative of the interval where water was released from or taken into storage during the simulation period. The specific yield of the zone dewatered or saturated during the period 1957 to 1977 was calculated for each driller log throughout the valley. In areas where no water level changes were experienced, specific yield was calculated for the interval from the static water level to approximately 50 feet below that water level.

Specific yield values generated and used as input ranged from 3 percent in the central portion of the alluvial basins, which is predominantly clay and sandy clay, to 25 percent in areas of abundant sand and gravel, such as along the Salt River. The specific yield values used as input are averages for each node from the zone map.

TRANSMISSIVITY

Transmissivity is a measure of the ability of an aquifer to transmit water. In the model it determines at what rates water will flow into and out of nodes.

Data Sources

Three sources of transmissivity data were available to the study. Values were obtained from (1) aquifer tests (2) estimates based on specific capacity values, and (3) estimates from the DWR Driller Log Program.

Data Estimates

Salt River Project Aquifer Test Program.

Salt River Project's pump test program calls for performance testing of all or selected wells within the Project boundaries every summer. In the summer of 1979, a cooperative program was initiated between the SRP, DWR, and

the USGS to obtain transmissivity, specific capacity and water quality data. Approximately 170 wells were tested between May and September of 1979. The typical test involved pumping the well for 24 hours and making measurements of the water-level recovery following shutdown until levels returned to near the static level. Transmissivity was calculated by straight-line techniques using either direct recovery or residual drawdown. Specific capacities were also calculated for each well and were used to determine the relationship between transmissivity and specific capacity. The tests were not long enough in duration, nor were there sufficient observation wells available to allow computation of specific yield data.

Transmissivity/Specific Capacity Relationship

Outside of the SRP boundaries, pump test data to determine transmissivity were scarce. Since specific capacity data, in these areas, were more abundant, the relationship between specific capacity and transmissivity was analyzed using aquifer test data from the 1979 SRP test program. The relationship which resulted from this analysis was used to estimate transmissivities utilizing specific capacity data from the areas outside SRP boundaries. This analysis was based on the fact that transmissivity and specific capacity are physically related because both are functions of the ability of the aquifer to transmit water. A plot of transmissivity and the corresponding specific capacity values yielded a straight line on log paper indicating the parameters were indeed related. A standard statistical program entitled "Curve-fitting", developed by Hewlett Packard, 1976 (Ref. No. 21), was applied to these data and resulted in the equation:

$$\text{Transmissivity} = 1972 \times (\text{Specific Capacity})^{\frac{1.085}{1.0185}}$$

This relationship was used to estimate transmissivity where specific capacity data were available, and pump test data were not.

The specific capacity data gathered for this study are generally reliable and accurate. With the exception of the SRP data, most of the specific capacities were derived from winter static water levels and from summer pumping levels. The predicted transmissivities from these specific capacities were compatible with available field transmissivity values.

DWR Driller Log Program

Transmissivity and specific capacity values were unavailable for some areas of the valley. Therefore, the DWR Driller Log Program was used to generate transmissivity values to fill data gaps. The DWR Driller Log Program assigns permeability values to each aquifer material type in the same manner in which specific yield is assigned. Transmissivity of each aquifer material type is calculated by multiplying the permeability of each described unit by the thickness of the material. The transmissivity values calculated for each material are summed from the water level to the total well depth to obtain a total transmissivity for the well. Static water-level data circa 1957 were used in the calculation of total transmissivity.

Transmissivity estimates from the DWR Driller Log Program have been used with success in several other modeling efforts. However, the computer estimates are still considered the least reliable source of data on transmissivity. Transmissivity values from aquifer tests and estimated from specific capacity data from field tests were used for comparison in several areas to assess the accuracy of the DWR Driller Log Program. Results were favorable; most generated values were within the relative transmissivity ranges chosen for mapping.

Data Input

A transmissivity map was produced showing zones corresponding to ranges of transmissivity. The ranges of

transmissivity used are: less than 25,000; 25,000 to 100,000; and greater than 100,000 GPD per foot. A grid map was placed over the zone map and an average transmissivity value was assigned to each active node. These transmissivity values were used as input for each node.

PUMPAGE

Pumpage is an essential parameter in modeling calculations. A concerted effort was made to obtain comprehensive pumpage data for all of the water users in the Salt River Valley. In general, water users in the SRV do not measure pumpage directly, but estimate it on an annual basis from power records or from records of number of hours a pump operated. Although a considerable volume of pumpage data was obtained, many gaps in the data exist.

Data Sources

The following water users provided data directly to the Department or the U.S. Geological Survey: Buckeye Irrigation District, Roosevelt Water Conservation District, Roosevelt Irrigation District, Salt River Project, Maricopa County Municipal Water Conservation District No. 1, Magma Engineering and Natural Gas Company, Luke and Williams Air Force Bases, and the Cities of Chandler, Glendale, Mesa, Phoenix, Scottsdale, and Tempe. In addition, numerous private water companies provided information including Adaman Mutual, Clearwater, Carefree, Litchfield Park, Sun City, North Valley, Arizona Water, Desert Sage, and Desert Hills.

Data Estimates

Although data was requested for the period 1957-1978, in many instances records were not available for particular years during this period or the water user had purchased a well and was uncertain of its pumpage history. In these cases, pumpage values were estimated by averaging data from years with

records. If a well had been purchased and the construction date and the pumpage history were uncertain, the well was assumed to have existed and been pumped since 1957.

Data Input

Pumpage is input to the model as the total pumpage per node. Files for the SRV model consist of total pumpage by node by calendar year for the years 1957-1978. Pumpage estimates for 1978, however, are not complete and values listed in the file need to be updated. Model documentation files include, in addition to grid designation for each node, the township, range, and section number for each node. Appendix Table No. A-1 is a listing of the pumpage values used in the model.

RECHARGE

Recharge varies considerably over the model area depending upon location and corresponding land use patterns. Recharge increases near river beds and decreases near hard rock areas and basin boundaries. Recharge is larger for nodes containing irrigated lands than for nodes of urban or undeveloped lands.

Data Sources

Recharge to the SRV was considered to occur from six sources: agricultural irrigation, non-agricultural irrigation, sewage effluent, flood flows, canal seepage, and subsurface inflow. Actual measurements of recharge from any of the potential recharge sources considered for this study are sparse to non-existent. Data on the distribution of recharge are also sparse, and data on the distribution by section are non-existent. Thus, recharge values for all types of recharge had to be estimated. Each type of recharge was estimated using different types of data. Consumptive use by crops and irrigation application rates were used to estimate

potential recharge from agricultural and non-agricultural irrigation. Water budget analyses were used to estimate recharge from sewage effluent, canal seepage, and flood flows. Flow net analyses were used to estimate subsurface inflow.

Crop distribution, acreage data, and application rate data were collected from Salt River Project files for Project lands and from the Department's files on Central Arizona Project applications for other irrigation districts and some private irrigators. Canal transmission loss data were also gathered for Salt River Project canals. Flood flow data were used from U.S. Geological Survey records. Additional data were also gathered from consultant reports from various projects throughout the SRV. Additional details on the type of data used and their source are included in the following descriptions of the estimation techniques used for each of the recharge types.

Data Estimates

Despite tedious analyses performed to obtain recharge figures for input into the model, values for this parameter are considered the weakest of all the data types used. This is due primarily to the fact that both recharge values and distributions had to be estimated because of the lack of measured data.

The lack of data includes items of the water budget that result in water being attributed to potential recharge that may actually be lost. These items of the budget include some evaporation losses, soil retention, excess irrigation application runoff as tailwater, bank storage in flood flows, and others. Thus, estimates of potential recharge derived from the simple water budget are higher than actual recharge. The values estimated for the project were not used as direct input to the model. Initial input was 50 percent of the estimated value and the original estimates served as an

upper limit to potential recharge as calibration progressed.

The recharge data developed for the SRV included an estimate of maximum potential recharge from each source for each node. The estimation technique for recharge from each of the six sources are described below.

Agricultural Irrigation

Recharge from agricultural irrigation was determined for irrigation districts and privately owned irrigated lands. The method of estimating potential recharge from agricultural irrigation varies among irrigation districts and private irrigators, mainly because of the difference in record keeping practices among these groups.

Irrigation Districts - For irrigation districts cropped acreages were obtained from Department files from data submitted by each district that applied for Central Arizona Project (CAP) allocations. Some files contained maps which displayed actual crop locations so estimated recharge values could be distributed accordingly. However, most files contained only total acreage for each crop with no indication of cropping patterns. In these instances, recharge values were distributed evenly over irrigated lands in the district.

The year 1969 was selected as a base year for agricultural irrigation data. Cropped acreage and distribution patterns were available for many of the irrigation districts for that year from the CAP applications. Lands in these districts constitute the bulk of the total irrigated land in SRV. For all irrigation districts other than SRP, the yearly potential recharge total was distributed by node for the years 1957-1977 according to the crop distributions indicated in the 1969 data.

However, data from SRP included detailed irrigated acreage data for 1969 and a detailed irrigated acreage map for 1975. The irrigated acreage distribution patterns of the two

years were compared by percentages of total acreage cultivated. In general, the patterns for the two years were quite similar, the major difference occurring in T1S, R4E, where 7.8 percent of irrigated land went out of cultivation between 1969 and 1975.

Using these two years as guidelines, the recharge values were distributed within SRP boundaries for 1957-1969 according to the 1969 distribution and distributed for 1970-1978 according to the 1975 data. The amount of recharge for each node was estimated using a simple water budget: potential recharge equals application rate minus consumptive use. The amount of water each district applied to crops was calculated by multiplying the acres of individual crop type by the appropriate application rate for that crop. Application rates for each crop type were obtained from an unpublished working file report provided to the Department in 1973 by Erie, French, and Harris, 1965 (Ref. No. 17). The amounts of water applied per crop were summed to yield the total water applied per district.

As a check on theoretical application rates, total water applied was compared to the water delivered to each district as reported in the CAP application file. Overall the calculated applied water values for the SRV basin were high by about 7 percent. This is a good correlation and well within the measurement error associated with the delivery estimates used in the CAP applications.

Consumptive use values used in the water budget analysis were values from studies done by the University of Arizona in Maricopa, Pinal and Pima Counties reported by Erie, French, and Harris, 1965 (Ref. No. 17). In areas where crop distributions were not available a weighted average consumptive use value was used. It was assumed cropping patterns were similar throughout the SRV. The weighted average consumptive use of the crop types reported in 1969 was 55 percent of the total water applied.

Privately Irrigated Lands - Privately irrigated lands are those lands where water is not delivered by an irrigation district but by individually owned wells. Data on crop and cropping patterns were not available for these lands. Recharge from these lands was estimated by applying the weighted average consumptive use values developed for irrigation districts of 55 percent. Thus, 45 percent of the total estimated private irrigation pumpage was estimated to be the maximum potential recharge on these lands.

Values of maximum potential recharge ranged from 1.2 to 2.5 acre-ft per irrigated acre. Delivery figures for organized irrigation districts do not include correction for irrigation tail water, thus delivery figures in the districts are higher than actual crop deliveries. Values of maximum potential recharge used in the model include double cropping effects where data were available.

The reliability of recharge values for agricultural irrigation was reduced by lack of specific data for each farming operation. For example, although application rates may vary significantly among farming operations, one standard application rate per crop was used in these estimates. Furthermore, crop distribution patterns are often unavailable resulting in annual recharge estimates being evenly distributed over the irrigated area. The inability to deal accurately with these factors reduces the reliability of these estimates, and as recharge estimates for agricultural irrigation generally constitute the largest portion of total recharge per node in most nodes, the reliability of the total recharge data used in the model are similarly reduced.

Non-Agricultural Irrigation

Recharge from non-agricultural irrigation originates from sources such as residential lawn irrigation and irrigation of parks, playgrounds, golf courses, industrial lands, townsites,

and tree rows. As with agricultural irrigation, determination of recharge values was based on consumptive use and application rate information on the plants involved (primarily grasses) and with the resulting estimates applied over the respective irrigated non-agricultural lands.

Available data indicate the consumptive use of Bermuda grass is about 3.6 AF/acre. In 1978 the average urban SRP user received 4.76 AF/acre for lawn flood irrigation. Assuming that other grasses consume about the same amount of water as Bermuda, this would leave a residual amount of 1.16 AF/acre, or 25 percent of the applied water, available as potential recharge. In 1978 the total water delivered for non-agricultural irrigation by all types of such users in the SRP area was 93,300 acre-ft. Potential recharge then equals 23,300 acre-ft. This was considered the total non-agricultural irrigation recharge for 1978 and was apportioned according to acreage distributions for this type of application found in a portion of the MAG 208 study. The figures generated were applied to all model years assuming few changes in non-agricultural distribution with time. Non-agricultural irrigation recharge was attributed only to acreages within the SRP boundaries as lawn irrigation outside the SRP boundary is assumed to be sprinkler type with a minimal application rate leaving an insignificant residual amount for recharge.

The reliability of the recharge figures used for non-agricultural irrigated lands are subject to problems similar to the recharge figures for agricultural irrigated lands; primarily the lack of specific data for the amount and the distribution of application to these irrigated areas. However, the effect of the inaccuracies on model calibration are very small because of the relatively minor amount of recharge water involved.

Sewage Effluent

Effluent is discharged into the Salt River Channel from sewage treatment plants at 23rd Avenue and 91st Avenue. During the simulation period 1972-1977, discharges from these plants averaged 37,300 acre-ft per year and 73,370 acre-ft per year, respectively.

Recharge from sewage effluent occurs between the 23rd Avenue treatment plant and the Buckeye heading. Sewage effluent from 23rd Avenue is conveyed to the Salt River Channel in a ditch to a point near 51st Avenue. From 51st Avenue the effluent follows the river channel to the Buckeye heading. A water budget study by Halpenny and Green (1975) estimated that about 80 percent of the 23rd Avenue effluent entered the groundwater system as recharge between the 23rd Avenue and the 91st Avenue plants. The report also stated that before the 1966-1967 flooding, 35 percent of the remaining flow in the Salt River Channel from the 23rd Avenue and the 91st Avenue effluent percolated to the groundwater between 91st Avenue and the Buckeye heading. After 1967, the recharge in this reach of the Salt River Channel decreased to 26 percent due to river bed rechannelization. The 26 percent figure was used to calculate recharge between 91st Avenue and the Buckeye heading for the period 1972-1977.

The nodes which received recharge from sewage effluent were determined from locations of the effluent discharge channel as shown on topographic maps. Total potential recharge estimates were then evenly distributed among the nodes in the two reaches for each year of the model simulation periods.

Flood Flows

Flood flows in the Salt-Gila River System in the SRV are another important source of recharge in the SRV. During periods of high runoff the normally dry channel of the Salt River carries large volumes of water resulting in considerable

infiltration losses in the channel. In order to estimate the amount of recharge from flood events, annual river flows volumes were obtained from USGS surface water records published by U.S. Geological Survey, 1961, 1970 and 1972-1975, (Ref. Nos. 50, 51, 52, 53, 54, 55, 56, and 57). These references provided flow measurements at the following points:

1. Salt River below Stewart Mountain Dam
2. Verde River near Scottsdale
3. Gila River near Laveen
4. Agua Fria River at Avondale
5. Gila River below Gillespie Dam
6. Diversions at Granite Reef into the Arizona and South Canals (This data was obtained from unpublished SRP water balance sheets for the years 1957-1974.)

Recharge from river flow was determined using the following equations:

- A. Salt River flow (1) + Verde River flow (2) - canal diversions (6) = channel flow downstream from Granite Reef.
- B. Gila River flow (5) - Agua Fria flow (4) - Gila River flow (3) = Channel flow at Gillespie Dam from Salt River.
- C. Channel flow downstream from Granite Reef (A) - Channel flow at Gillespie Dam (B) = total amount available for channel recharge in model area.

A total of 74 model nodes underlie the Salt River Channel from Granite Reef to the confluence of the Salt and Gila Rivers. The total amount of streamflow loss available for recharge was equally apportioned among these nodes. Total streamflow loss recharge ranged from zero in non-flood years to 330,000 acre-ft in 1973. In the western portion of the SRV downstream of the confluence of the Salt and Gila Rivers, the static water levels are generally at or near land surface; therefore, infiltration from excess stream flow is negligible in this area.

Canal Seepage

Canal seepage is a source of substantial potential recharge in the SRV due to the number and extent of unlined canals. Seepage estimates were made for the Salt River Project canal system, which includes many of the major canals in the model area. Although other irrigation districts also maintain canal systems, seepage could not be estimated for these because the necessary records are not available.

Potential recharge from canal seepage in the SRP system was calculated by subtracting flow measurements at lateral heads from flow at the heads of main canals. The resultant values were distributed equally among model nodes along the length of the system.

The canals considered in this analysis were: Granite Reef to Arizona Falls below Powerhouse, Arizona Canal below Powerhouse, Grand Canal below Powerhouse, Tempe-Western-Kyrene-Highline Canal System, East Branch Consolidated Canal System, Eastern Canal, and Granite Reef Dam to the Diversion Gates. Since evaporation losses were not considered, the seepage values generated here represent maximum potential recharge.

Subsurface Inflow

Recharge in the SRV is not confined to infiltration of water on the surface. A small amount of recharge is also derived from subsurface inflow in those areas on the perimeter of the SRV including northwest of Beardsley, northern Paradise Valley, Florence Junction, west of the San Tan Mountains, and near Komatke. Near Buckeye, boundary conditions vary. Northeast of Buckeye, boundary flow is generally toward the SRV west basin and the cone of depression near Luke Air Force Base. However, there is an area of outflow along the Salt River Channel east of Buckeye in section 30 T1N R3E. Both components of flow were calculated. Results showed that there was a small net inflow along the boundary in this area. This

net inflow was applied as recharge to the appropriate boundary nodes.

Flow for each boundary node was input as constant flow and was established in the following manner: (1) total flow across the boundary was determined by flow net analysis using a weighted average transmissivity for the length of the boundary; (2) the flow for each node was calculated using transmissivity, node width, and hydraulic gradients obtained from water-level maps. The results of the calculations from one or both methods of analysis have been listed in Figure 1.

*Computed values were not reliable due to errors in the water-level maps.

**In the Buckeye area the boundary is complex. North of the Gila River Channel groundwater flows toward the cone of depression in the Luke-Goodyear area. In the vicinity of the river channel groundwater flows down the natural drainage of the Gila River. Both components were considered in the analysis.

In general, the 1964 water-level elevation contour map, from which flow net calculations were made, was the earliest reliable map. In northern Paradise Valley, the 1964 map was insufficient due to a lack of data in T4N, R4E, near the model boundary. As a result, the 1976 map was used to determine subsurface inflow in this area. The flow estimate for the Northern Paradise Valley area is less than reported by Arteaga, White, Cooley and Suthierner, 1968 (Ref. No. 3). The difference is due to the location of the cross section used for the flow net and different estimates of transmissivity made during SRV Cooperative Study.

Anomalously high flow rates were calculated in the area just west of the San Tan Mountains. Flow from this area to the north was calculated to be about 96,000 acre-ft/yr on the basis of flow net analyses using data from the USGS 1964 contour map. A flow of this magnitude was considered highly unlikely. It was suspected that this map showed contours of a perched zone (appearing as a groundwater dome) rather than the regional aquifer. The flow volume used in the model, 2,000 acre-ft/yr, which was obtained from a flow net analysis performed on the 1964 Bureau of Reclamation groundwater elevation map prepared for the Central Arizona Project environmental reports, appeared far more reasonable considering the hydrologic conditions of this area. This discovery led to changes to the groundwater elevation node maps in this area for the years 1964, 1969 and 1972. Portions of the 1964 and 1972 USGS maps were recontoured to remove the contours of the perched zone.

Outflow occurs in only one small area, north of Buckeye, where the model boundary crosses a groundwater divide in the Buckeye-Liberty area. To the north of Liberty there is a remnant of the natural gradient to the west out of the modeled area. Most of the subsurface flow, however, has been reversed due to intense pumping in the Goodyear-Avondale-Luke area. Since the amount of outflow was small, it was subtracted from

total inflow to yield a net inflow into the modeled area; this net amount was applied as recharge along the boundary.

To sum up this discussion then, subsurface inflow values are estimates as are all of the recharge values used in the modeling effort. These estimates are based on groundwater elevation contours and other data which may not be reliable. These values cannot be improved significantly until additional water-level data, water use data, and aquifer data from pump tests become available.

It is essential to stress that, in general, all types of recharge are estimates of the maximum potential water available for recharge. The values calculated for the modeling process were intended for use as the upper limit of recharge available in the calibration phase of the model only. The values indicated should not be construed as absolute estimates of actual recharge.

Data Input

The original recharge estimates from each of the various sources were summed for each node and varying proportions of the total were used as model input. The values represent the maximum potential recharge per node per year, and are listed in Table A-2.

CHAPTER III MODEL RESULTS

The results of the model effort are discussed in terms of the calibration period and accuracy of the resulting model. The capabilities of the calibrated model are discussed in Chapter IV.

After data input for the model was prepared, numerous model runs were made to calibrate each of the four originally selected simulation periods. During the calibration process, each of the five basic input data types were carefully evaluated and reasonable changes made as required. After much

effort, it was determined that the input data would allow calibration for only one simulation period, 1972-1977. The values of the data that yielded the best match of model and measured (and estimated) values in the calibration process are presented in tabular form. These values are considered to be the best estimates of various types of data currently available.

Knowledge of the accuracy of the calibrated model is imperative for its use as a management tool. The accuracy of a model is judged in terms of its ability to reproduce measured water-level configurations within a given error range. The selected error criteria and the water levels produced by the model are discussed in detail in the following sections.

CALIBRATION OF THE MODEL

Calibration of the model involved adjusting the values of the model input parameters so that the differences in calculated versus measured groundwater elevations for the end of the simulation period were minimized. The order in which the different types of data were to be changed was based on initial assumptions as to their reliability, and the changes were limited to stay within reasonable limits for the value of each parameter. This order, from the most to the least reliable, was as follows:

1. groundwater elevations
2. pumpage
3. transmissivity
4. specific yield
5. recharge

In addition to decisions on changes in the hydrologic parameters involved in calibration, a decision had to be made as to when the model was sufficiently calibrated. Models cannot be calibrated to 100 percent accuracy because a model is never as complex as the system simulated. One of the functions of the modeler is to simplify a complex system by

dividing it into less complex components which can be defined by approximations (mathematical in this case). Models are judged to be accurate (or sufficiently calibrated) when the simulated results approximate the measured results within acceptable error criteria. Acceptable error, different for each model, is generally defined by the modeler and is dependent on the accuracy of the input data. The errors associated with each of the data input types indicate the accuracy that may be achieved. For example, if water-level elevations are accurate to within plus or minus 10 feet, the model should not be expected to be more accurate.

The acceptable error criteria is generally controlled solely by the accuracy of the input data. However, the number of calibration attempts to reach the error criteria is controlled by the sensitivity of the model to changes in input data. Shortcomings of the model, such as inadequate data or wrong assumptions in the conceptual model, may make it impossible to reach the desired error criteria. In this case, calibration attempts are terminated when reasonable changes in the input parameters cease to make significant improvement in the model results.

In the SRV model study, the average error was one of the criteria used to evaluate model accuracy for calibration. Error is defined as the difference between the calculated water levels and the measured water levels at the end of the simulation period. This indicator is only a guide and must be evaluated with full consideration of the distribution of error in the system. Understanding the areas where large errors occur and the reason for the errors is important to the interpretation of the model results.

A value of ten feet was chosen as acceptable error because it represents the possible error in water-level elevation data. It is unreasonable to expect the model to calibrate closer than the possible errors in the primary input data.

Calibration changes in the input parameters were made only within reasonable values, reasonable values being the estimated range of minimum to maximum for each parameter described in the data collection efforts, and documented ranges of values in published literature. (Example: estimates of specific yield used in calibration ranged from .01 to .25). Within these criteria, much of the model did not calibrate to within the acceptable error criteria. Much of the model did, however, react as the natural system did and errors did not exceed the acceptable error by large amounts.

It was originally assumed that recharge values would be changed first followed by specific yield, if it became necessary. However, contrary to what would be expected, initial calibration attempts indicated that several areas in the valley had water-level rises or insufficient declines in areas of large development. Model runs for the periods 1964-1969, 1969-1972, and 1972-1977 all showed significant problems with calibration. Many areas in the model simulation declined where the water-level contour maps showed rises. Normal calibration procedures (varying recharge, specific yield and/or transmissivity) would not cure the problem. To achieve water-level elevation rises required by the initial calibration attempts, inflow would have to exceed outflow, i.e., recharge would have to exceed pumpage. As the data gathered for estimating these parameters indicated that this was impossible, groundwater elevations and flow patterns were reviewed.

There are several possible explanations for these problems. There could be errors in groundwater elevation data, coding, and contours; or water level rises may not occur throughout the aquifer, that is, the water level rises may only occur locally in perched zones.

In an attempt to identify which of these problems existed in the water-level data, the actual measurements used in the original maps were gathered and plotted. Measurements for the

1964 and 1969 maps were sparse and were little help in determining why there were major differences in these maps. Thus, attempts to calibrate 1964-1969 and 1969-1972 periods were abandoned.

The water-level data obtained from the U.S. Bureau of Reclamation records for the 1972 water-level map revealed no apparent errors and the data obtained matched the contour maps in most cases. However, on close inspection of the 1972 and 1976 contour maps, it became clear that the contours on the maps were drawn employing different assumptions. Contour maps are drawn ing the available data and an assumption of how the groundwater flow system works, i.e., the contours are drawn to predetermined patterns employed by the various authors, none of which have the benefit of an actual model. The problem with the 1972 to 1977 simulation period was partially solved by recontouring the 1972 map using the 1976 to 1977 USGS maps by Laney, Ross, and Littin, 1978 (Ref. No. 25) and Ross, 1978 (Ref. No. 38) as a guide, as it was felt that these authors had the most and best data available to them when they drew the maps.

After recontouring the 1972 water-level data, the model simulated water levels were in much better agreement with the measured data; therefore, calibration resumed as originally envisioned. Recharge was added or subtracted to nodes according to what the model required to reach calibration. If the model calculated more decline in groundwater elevations in a particular node than actually occurred, recharge was added based on the prevailing geologic and hydrologic conditions and judgement. Where the model calculated too little decline, or calculated more rise than actually occurred, water was removed from the node usually by reducing the recharge from that initially estimated for the nodes in question. The initial recharge values were considered maximum potential values; and, therefore, areas that required additional recharge were scrutinized, and more water was added only if additional

sources of recharge were found to exist.

In order to alter the effects that changes in pumpage or recharge had on groundwater elevations, the specific yields of the nodes involved were modified. For example, if reasonable decreases in recharge didn't result in a corresponding lowering of groundwater elevations, the specific yield was lowered, providing this change was judged reasonable.

Transmissivity was changed when it was necessary to change the rate of flow of water from one area to another or simulate gradient changes. However, it was found that changes in transmissivity did not have significant effects on the model.

As changes to recharge, specific yield, and transmissivity were sufficient to calibrate the model for the simulation period 1972-1977, and because of the reliability of the pumpage data collected, pumpage values were not changed from the initial input values.

CALIBRATED RESULTS

Final Recharge Values

The SRV has several complex recharge mechanisms. The Salt River Channel, where large amounts of recharge occur, is a good example. Initially, it would appear that flood flows are the source of the recharge in the channel. Closer inspection shows recharge sources in the river channel also include sewage effluent discharges from the 91st and 23rd Avenue treatment plants, urban runoff and irrigation tailwater. Estimating recharge from agricultural irrigation is also more complex than simply computing the residual from application rate and consumptive use. Several potential sources of recharge are associated with agriculture, such as canal seepage and tailwater which may or may not be reused. Because of this complex system, recharge values used for model calibration can only be approximately determined. Only the

two largest sources, streamflow from effluent and flood flow and agricultural irrigation, appear to have direct correlation with the recharge distribution used in model calibration.

Flood Flows (River Channel Recharge) - The highest recharge values associated with flood flows are found in the Salt River Channel. In the Salt-Gila River Channel, average annual recharge is about 1,250 acre-feet per channel mile per year during the 1972 to 1976/77 simulation period. Flood flow recharge in the Salt River Channel, estimated in acre-feet per square mile per year, occurs along the southern border of the Salt River Indian reservation, in the area north of Tempe-Mesa and in the areas south of Maryvale and Tolleson.

In the West Basin, an area of high recharge values outside the Salt River Channel, in the central part of the basin, is presumably associated with flood flows from the New and Agua Fria Rivers. However, there is considerable agricultural development in this area which contributes to the total recharge. Evaluation of the proportion of the total recharge attributable to flood flows of the New and Agua Fria Rivers is not possible due to the lack of detailed stream flow data for this area.

Recharge From Agricultural Irrigation and Canal Seepage - In the East Basin, recharge other than flood flow recharge occurs primarily in the Salt River Project area and in the Queen Creek area. Two small areas of high recharge, where values exceeded 2,000 acre-feet per square mile per year during the 1972 through 1976/77 simulation period, are located south of Mesa and Chandler. The high recharge was presumably due to a combination of agricultural irrigation and canal seepage. Another area of high recharge is located in northern Scottsdale, possibly due to seepage from the Arizona Canal. In the central portions of the SRP and Queen Creek, agricultural area average annual recharge values range between 1,000 and 2,000 acre-feet per square mile per year. In other

agricultural areas of the East Basin recharge values generally range from a few hundred to two thousand acre-feet per square mile per year.

In the West Basin, agricultural areas contribute significant recharge to the groundwater system in the Buckeye area, north of the Gila River Channel, the Goodyear-Tolleson area, and the McMicken Irrigation District. All of these areas are near major stream channels of the Salt, Agua Fria or New Rivers and thus, the amount of recharge from agriculture versus the amount from flood flow infiltration is difficult to assess. In some areas, such as northeast of Buckeye, water quality changes have indicated that irrigation return flow is contributing nitrate rich waters due to the use of sewage effluent for crop irrigation. However, it is difficult to evaluate the proportion of recharge from agricultural irrigation (using effluent as part of the supply) versus the recharge from effluent discharge in the river channel and transport in unlined canals because both sources are high in nitrate concentration. In areas away from the stream channels, recharge in the West Basin is similar to that in the East Basin and average annual recharge ranged from a few hundred to a few thousand acre-feet per year per square mile during the 1972 to 1976/77 simulation period.

The SRV Cooperative Study has attempted to define the types of recharge and the maximum potential values associated with each type. However, the model uses only total recharge in the finite difference approximation, thus the values used in the modeling effort are reasonable but are only estimates which satisfy this modeling effort. For that reason, no attempts have been made to separate the final recharge values into the recharge types used to estimate the total. Table A-3 lists the calibrated total recharge values.

Final Specific Yield Values

Most of the changes made in specific yield values during

calibration were small in absolute terms, but large relatively. For example, if specific yield for one node is changed from 10 percent to 12 percent, an absolute increase of only 2 percent, the relative change is an increase of 20 percent which is the degree of response felt by the model.

The general patterns of specific yield, throughout the SRV, based on the ranges initially established have changed little during calibration. Specific yield values are moderate to high (10 to 25 percent) along the present and historic river channels. Present channels include Salt, Gila, Agua Fria and New Rivers. Also included are the apparent ancestral channels of the Salt River in the Mesa-Chandler area and old channels of the Agua Fria and New River near Union Hills. Low to moderate values of specific yield (0 to 10 percent) are found in the central portions of the East and West Basins, such as the southern Paradise Valley and the Glendale and Beardsley areas. Table A-4 lists specific yield values that were used in the final calibration attempt.

Final Transmissivity Values

Transmissivity values range widely over the modeled area. Initially, three transmissivity value ranges were established to aide in identifying relative transmissivity zones. The ranges considered for this study were: low: less than 25,000 gpd/ft (gallons per day per foot); medium: 25,000 to 100,000 gpd/ft; and high: greater than 100,000 gpd/ft. Table A-4 also lists, by township, range, and section numbers, transmissivity values used in the final calibration attempt.

During the calibration effort, it was found that order of magnitude changes in transmissivity are necessary to cause significant changes in the water-level elevations calculated by the model. Because of this insensitivity, transmissivity patterns were not changed significantly from the initial data input. Transmissivity values were low to moderate at the bases of mountain fronts and high in areas along river

channels, similar to specific yield. There were low transmissivity values throughout northern and central Paradise Valley, parts of the Glendale-Deer Valley area, and the Luke Air Force Base-Litchfield Park area. There are indications that there may be low transmissivity values in some parts of the southeastern SRV, based on results of the DWR Aquifer Parameter Program. Calibration did not change the transmissivities in this area because there was little change in water levels and very little stress in this area during the simulation period.

One area that required significant changes in transmissivity values was the area between the cone of depression near Luke Air Force Base and the Salt River Channel. Extensive pumping in the Luke area and large amounts of recharge in the southern part of the area, along the Salt River, have produced a steep gradient between the river and the cone of depression. The steep gradient in this area is primarily due to the layering of the aquifer materials. The coarse grained river sediments collect large amounts of recharge which are not readily transmitted to the lower portions of the aquifer which are comprised of much finer material. Thus, a steep gradient is necessary to move water from the river channel area to the Luke area. The variation in sediment type with depth and the steep gradient of the water-level surface indicate that the groundwater flow is primarily vertical in this area. The transmissivity values used in this study are predominantly estimates of horizontal flow characteristics of the aquifer and do not adequately represent the aquifer system in this area. In order to approximate the vertical flow occurring in the aquifer system, a series of low transmissivity nodes was placed between the river and the cone of depression near Luke. These changes in transmissivity values were one to two orders of magnitude lower than the original estimates. The manipulation of transmissivity in this area improved the simulation but did not completely correct the problem because the two-dimensional

solution is not adequate to simulate a three-dimensional system.

Final Pumpage Values

Pumpage values estimated for the model study are based on the best available data from each of the water users. No changes in pumpage patterns or values were made during calibration (See Table No. A-1).

MODEL ACCURACY

The accuracy of the SRV Cooperative Study model may be evaluated by the model's ability to duplicate observed water levels and to reproduce the water table configurations measured in the real system. The difference between measured and simulated water levels is called error; ideally, the entire model area should calibrate to within the plus or minus a ten-foot error criteria.

Table No. A-5 is a listing, by township, range, and section, of beginning (1972), measured ending (1976-1977), and calculated ending (1976-1977) water-level elevation values. Also listed are the differences in measured and calculated ending water level. This difference is the error used in evaluating model performance.

Plate No. 2 shows the areas where the error is greater than 25 feet. Close inspection of the geology and hydrology of the areas of significant error indicates similar geohydrologic patterns. The largest errors occur where groundwater levels are very near the land surface and are adjacent to the areas of steep gradients such as north of the Goodyear-Avondale-Tolleson areas and near the Tempe Narrows in the Scottsdale area. Both of these areas have a large source of recharge along the Salt River Channel adjacent to a major cone of depression. Also, both are characterized by significant vertical variations in aquifer material. Typically, very coarse river alluvium overlays sandy clay or

silty clay in the areas of recharge (the river channel) and intermixed sand, silt, and clay in the cones of depression. The reason for the large error associated with this geologic configuration is the layered system beneath the river channel. The layers in these areas have large relative differences in vertical permeability (possibly two to three orders of magnitude). Most of the test data in the area are from wells that are open to the highly transmissive Salt River gravels; the wells do not penetrate the underlying fine-grained units. Even though the system is under water-table conditions, the communication between the upper and lower material is poor; and over short periods of time, it appears to be two systems.

The two-dimensional model used for the SRV modeling effort does not reflect this system well. The model is intended to simulate horizontal flow, not the vertical flow, which apparently is occurring in these areas. The water recharged in the river channel is affected by changes in vertical permeability, which the two dimensional model used does not portray. The high horizontal permeabilities used in the model, as estimated from test data, allow recharged water to be transmitted to the nearby withdrawal areas too readily. This lowers the simulated water levels beneath the river channel and raises the simulated water levels in the withdrawal area opposite of what is observed in the measured water levels.

Problems such as these may possibly be modeled using layered two-dimensional models or three-dimensional models. However, these models require more information for the various layers than is available at this time. With implementation of the data collection efforts outlined in the "Data Improvement" section, a subsequent attempt at layered or three-dimensional modeling may be possible.

In addition to error, a comparison of the contour configurations of simulated and measured elevations are

helpful in assessing the model's accuracy. The configuration of the simulated water-level elevation contours should be very similar to the measured water-level elevation contours. Plate No. 3 is a contour map of simulated 1976-1977 water-level elevations. Comparison of this map with the USGS water-level elevation map, Plate No. 1, indicates that the spatial relationships of the contours and the direction of flow are correct. However, some of the gradients are different due to the errors described above. The similarity of these maps indicates the model is reacting to stress and changes in stress in the same manner as the real system in most of the area. The differences in gradients and magnitudes of the respective declines and rises in the model are the results of poorly defined aquifer parameters, water-level data and recharge or pumpage information.

As can be seen from comparison of the maps, the SRV model is sufficiently accurate to obtain a general understanding of the system and its response to stress or changes in stress in most of the modeled area. However, when the model is used as a planning tool, those areas where errors exceed 25 feet over the simulation period must be reviewed carefully because predicted values in these areas will be less reliable. The model can be improved with additional work and reorientation of some of the data gathering efforts to provide information on vertical head differences.

CHAPTER IV MODEL DEVELOPMENT AND CAPABILITIES

As developed for Phase II, the computer programs for the model of the SRV required changes to input parameters on a node by node basis. Predictive modeling requires the capability to change input data arrays, especially pumpage and recharge, over large areas and many nodes to evaluate alternative plans for the future. To simplify the use of the model for predictive uses requires flexibility and ease in input data changes. Recent changes have been made to the SRV Cooperative Study model in preparation for its use as a

planning and management tool. These changes consist of modifications to the programs that manage the data base and changes to the model's program.

The modified data base programs identify pumpage and recharge by type, by location and by year. Two types of pumpage are listed, agricultural and municipal. Recharge is separated into five types: recharge related to agricultural applications; recharge related to municipal uses (effluent); natural recharge and flood flows; canal seepage; and residential irrigation. These changes allow the data base to be searched to provide useful summaries of historic pumpage and recharge by type and will provide a base for modifications of extrapolations of the data as desired for use in projecting future conditions.

The model's program has been modified to allow predictive runs to be made with the model utilizing user-selected projection period lengths and output formats. The user can select from options for the printing of drawdown maps and section by section information on aquifer parameters, pumpage, recharge, and water level changes.

There are a variety of uses for which the model has an immediate application. These applications consist of short-term projections, five to ten years in length, to simulate relative effects of changing pumping amounts and locations. For example, pumping patterns of municipal or agricultural well fields can be determined to minimize short-term water-level declines, and thus, minimize power consumption. Installation of new wells or well fields can be simulated to determine interference effects on other groundwater users in the immediate vicinity. Although the model deals only with water quantities, the supporting data on water quality can be used in conjunction with model projections to evaluate potential changes in groundwater quality in a well field over time. Short-term simulations minimize the cumulative effects of the errors in the model. As better and more plentiful data

become available in the future, the length and detail of future projections can be expanded.

Accurate depictions of future conditions further into the future are dependent upon how accurately the future demands for water and recharge from the various sources can be predicted, as well as the accuracy with which aquifer conditions are described in the model. Aquifer conditions vary areally and with depth so that as water levels decline, the data in the model describing current conditions becomes less and less appropriate. Knowledge of these changing conditions can be obtained through continued, careful data collection and analysis as new wells are drilled throughout the area.

Multiple model simulations can be made to compare the impacts of a variety of alternative development plans, or to plan data collection efforts necessary to improve the accuracy of the model. Used in this fashion, model predictions of water-level change will provide precise information on the difference in impacts between alternatives or the sensitivity of the model to data errors over any time period, short or long.

CHAPTER V RECOMMENDATIONS

The data deficiencies encountered in this study and recommendations concerning these deficiencies are categorized according to 1) data needs; and 2) data improvement. Prior to completion of this model, Senate Bill 1001, the Groundwater Management Act, was enacted by the State Legislature. The legislation has placed added responsibility on the modeling study cooperators and other water users in the SRV. As a result of this act, water users in the Phoenix AMA are required to furnish data to the DWR on their annual groundwater pumpage, new well construction data, and aquifer test data. The filing of such data in compliance with the law will allow updating of the SRV model through expanded data

collection efforts necessary to monitor compliance with the management plan.

The data collection and reporting techniques recommended in this section were developed in response to provisions of the new law. These procedures as they are developed will be coordinated with the Phoenix AMA reporting requirements to provide maximum use of data and to prevent duplication of effort.

DATA NEEDS

In order to make the model more reliable, certain data needs must be satisfied. Two periods of time may be established as having different data requirements: 1) the period since the last calibration (1977 to 1982); and 2) the future periods.

Updating the model for the current period would require the continuation of data collection efforts initiated for this report. This effort will include the collection of pumpage information for the intervening years, 1978 through 1982, an inventory of new wells drilled since 1978, and an examination of changes in land use patterns since 1978. Information collected during the floods of 1978, 1979, and 1980 and additional water quality data would also be evaluated.

Future data needs center around the three-dimensional nature of the aquifer system. For example, delineation of changes in hydraulic head with depth would define the vertical flow components that occur in the system in response to stress. Changes in water quality and permeability with depth also need to be identified. These poorly quantified items should have a high priority in future data collection programs.

Presented below are the types of data required. These data requirements apply to both the current and future periods. The requirements include physical well data, pumpage

data, irrigated acreage data, well test data, and water quality data. The appropriate unit of measure for each data type requested is included in parenthesis, and the proper form, for data required by the new code, is referenced. Copies of the forms referred to are included in the appendix.

Physical Well Data (Required by A.R.S. 45-600) Form - Well Driller Report

Local number and state location (township, range, section, 1/4, 1/4, 1/4, section of well)

Driller and other logs

Construction and Performance data

Date drilled
Depth (ft)
Casing diameter (in)
Depth cased (ft)
Perforated interval(s) (ft)
Type of perforation(s)
Method of drilling (cable tool, rotary, etc.)
Static water level (ft)

Status of well

Active
Abandoned

Pumpage Data (Required for a Well with Greater Than 35 GPM Capacity, A.R.S. 45-632) Form (Not Yet Available)

Amount of pumpage (acre-ft)
Method of measurement (type of metering device)
Use of water pumped

Agricultural irrigation
Industrial
Municipal

Irrigated Acreage Data (Required by A.R.S. 45-465) Form -
Grandfathered Rights Application

Acreage by crop (if possible)
Distribution/location patterns of crops
Crop application rate (acre-ft per acre per year)
Estimate of tailwater lost from system (acre-ft)
Estimates of canal/lateral losses (acre-ft)

Note: The data listed were required by law for Grandfathered Rights Applications. However, the requirement was for the application period only; and some of these data are voluntary. The data, if gathered and kept by the water user, will be very helpful in future modeling and planning efforts.

Well Test Data (Required by A.R.S. 45-600) Form - Completion Report

Well performance tests

Static water level (feet below land surface); this should not be a flash static; data and method of measurement (airline, sounder, etc.)
Pumping water level (feet below land surface)
Discharge (gpm); method used (orifice, flow meter)
Specific capacity (GPM/ft of drawdown)

Aquifer testing (not required by law) if available

Static water level (feet below land surface); this should not be a flash static; data and method of measurement (airline, sounder, etc.)
Pumping water level (feet below land surface)
Discharge (gpm); method used (orifice, venturi meter)
Specific capacity (GPM/ft of drawdown)
Time drawdown data
Distance drawdown data
Description of observation well including all physical well data as mentioned in category A
Distance to observation well

Water Quality (Not Required by Law)

Sample depth
Sampling Procedure
Results of chemical analyses
Name of testing lab
Well location and date of analyses for each sample
Discharge when sample taken
Duration of pumping prior to sampling

DATA IMPROVEMENT

In addition to the expanded groundwater data collection efforts in the future, there is also a need to improve the quality of data. For example, many problems encountered in this modeling effort have been related to water levels or groundwater elevations. Water levels should only be measured in wells where sufficient physical well data, such as the well depth, diameter, and perforated intervals are available. This type of information can be used in identifying, and therefore, separating measurements of regional water levels from perched water levels. It is also useful to include information such as the proximity of pumping wells as a means of establishing the validity of static water-level measurements.

Careful documentation of data gathering and testing procedures cannot be underestimated. A description of the steps used in data gathering can provide information concerning bias in the data, if any exists. Standardized procedures should be followed, standard terms should be used in discussing results and standard dimensional units should be used in reporting data. This will produce a consistent data base that is efficiently stored with a minimum of error and is useful to a variety of interests.

This can be done by establishing and using standard groundwater data collection procedures as described in a variety of standard methods manuals. An excellent example of this type of manual is "National Handbook of Recommended Methods for Water-Data Acquisition" (U.S.G.S., 1980).

CHAPTER VI CONCLUSIONS

The SRV Cooperative Study has developed a comprehensive data base comprised of groundwater, aquifer, and water use data collected from most of the major water users in the Salt River Valley. This aggregate of information has been used to build and calibrate a two-dimensional groundwater flow model

of the aquifer systems of the Salt River Valley. The groundwater model accuracy is generally good and simulates groundwater flow conditions for the years 1972 thru 1977. During the modeling efforts, several data deficiencies were noted which affect the accuracy of the model and limit understanding of the aquifer system in portions of the SRV. Notwithstanding these deficiencies, the SRV model is the best analytical tool available for evaluating conditions and response of the aquifers in the SRV. As such, the model may be used for planning purposes for the near future, ten years or less, with confidence that the model will react similar to the actual system, although the amount of change the model predicts must be evaluated in light of the potential error associated with the model.

The SRV Cooperative Study model can be significantly improved with data gathered in a program such as the one recommended in this report. Periodic update of the SRV model using data collected in the efforts described, and using the knowledge gained from the collection efforts, will provide a better planning tool. It will provide more accurate simulation and longer simulation periods. This will improve the confidence level with which the model may be used, and extend the projection time period that can be modeled with confidence.

GLOSSARY OF TERMS

A number of terms used in this report are defined below. The definitions were modified from Lohman and others (1972).

Aquifer -- A geologic formation, group of formations, or part of a formation that contains sufficient saturated permeable material to yield significant quantities of water to wells and springs.

Artesian aquifer -- See confined aquifer.

Confined aquifer -- An aquifer in which groundwater is confined under pressure significantly greater than atmospheric pressure; artesian conditions. Synonym: artesian aquifer.

Discharge -- The processes by which water leaves an aquifer.

Flow line -- The path that a particle of water follows in its movement through saturated, permeable rocks.

Groundwater divide -- A ridge in the water table or other potentiometric surface across which groundwater does not flow.

Groundwater model -- A mathematical representation of a groundwater flow system.

Head -- The height above a standard datum of the surface of a column of water that can be supported by the pressure at a given point in an aquifer. In this report, head is referred to National Geodetic Vertical Datum of 1929. See potentiometric surface.

Hydraulic conductivity -- The rate at which water is transmitted through a unit cross-sectional area of an aquifer under a unit hydraulic gradient. It describes the ability of the aquifer material to transmit water, and it may have substantially different values in the horizontal and vertical directions.

Hydraulic gradient -- The change in static head per unit of distance in a given direction.

Potentiometric surface -- A surface representing the hydraulic head in an aquifer. In an unconfined aquifer this is the water table. In a confined aquifer, it is represented by the level at which water would stand in tightly cased wells.

Recharge -- The processes by which water enters an aquifer.

Specific capacity -- The specific capacity of a well is the rate of discharge of water from the well divided by the drawdown of water level within the well.

Specific yield -- Of a rock or soil has been defined as the ratio of (1) the volume of water which the rock or soil, after being saturated, will yield by gravity to (2) the volume of the rock or soil.

Steady state model -- A model of a system in equilibrium, in groundwater modeling a model of an aquifer system in which inflow to the system equals outflow from the system with no change in storage. Usually used for calibrating transmissivity or hydraulic conductivity.

Storage -- In groundwater hydrology, this term refers to water detained in a groundwater reservoir.

Storage coefficient -- The volume of water an aquifer releases from or takes into storage per unit surface area of the aquifer per unit change in head. In a confined aquifer, the storage coefficient reflects release from storage due to compression of the aquifer and expansion of water. See also specific yield.

Transmissivity -- The rate at which water is transmitted through a unit width of an aquifer under a unit hydraulic gradient. It describes the ability of the entire thickness of an aquifer to transmit water. Transmissivity is the product of hydraulic conductivity and thickness of the aquifer.

Unconfined aquifer -- An aquifer having a water table. Synonym: water-table aquifer. See water-table aquifer.

Water budget -- An accounting of the recharge, discharge, and storage changes in a hydrologic system.

Water-level elevation -- Elevation of the water level above mean sea level. See also head.

Water table -- The water surface in an unconfined aquifer at which the pressure is equal to atmospheric. It is the water level in wells that penetrate the uppermost part of an unconfined aquifer.

Water-table aquifer -- See unconfined aquifer.

WELL DRILLER REPORT

This report should be prepared by the driller in all detail and filed with the Department within 30 days following completion of the well.

1. Owner _____ Name _____

Address _____

2. Lessee or Operator _____ Name _____

Address _____

3. Driller _____ Name _____

Address _____

4. Location of well: _____

5. Permit No. _____ (if issued) _____

DESCRIPTION OF WELL

6. Total depth of hole _____ ft.

7. Type of Casing _____

8. Diameter and length of casing _____ in. from _____ to _____, _____ in from _____ to _____

9. Method of sealing at reduction points _____

10. Perforated from _____ to _____, from _____ to _____, from _____ to _____

1. Size of cuts _____

2. If screen was installed: Lenr Date.....

2-73

3. Method of construction _____

4. Date started _____ Month _____

5. Date completed _____ Mo- Driller.....

6. Depth to water _____

7. Describe po- available _____

I hereby certify that this well was drilled by me (or under my supervis herein contained are true to the best of my knowledge and belief.

OFFICIAL APPLICATION FORMS
FOR
GRANDFATHERED GROUNDWATER RIGHTS

STATE OF ARIZONA
DEPARTMENT OF WATER RESOURCES
P. O. Box 2600
Phoenix, Arizona 85002

COMPLETED APPLICATIONS MUST BE MAILED BY
SEPTEMBER 14, 1981

YOUR GROUNDWATER RIGHTS

The future use of groundwater by current water users may depend on acquiring a Certificate of Grandfathered Right. This information will help you to decide if you need to apply for a certificate. Read it carefully.

A NEW SYSTEM OF GROUNDWATER RIGHTS FOR ARIZONA

For years Arizonans have been using water more rapidly than nature has replenished it. This has been possible only through massive withdrawals of water banked as groundwater reserves in the long distant past. Groundwater – that is, water withdrawn from beneath the ground – accounts for about two thirds of the water used in Arizona. In many parts of the State, these massive withdrawals, or “overdrafts”, of groundwater have led to higher costs of pumping groundwater, earth cracks and the deterioration of water quality. After years of increasing concern for these problems, the Arizona Legislature passed the Arizona Groundwater Management Act. Governor Bruce Babbitt signed the Act into law on June 12, 1980.

In passing this new law, the Legislature declared that “in the interest of protecting and stabilizing the general economy and welfare of this state and its citizens it is necessary to conserve, protect and allocate the use of groundwater resources of the state and to provide a framework for the comprehensive management and regulation of . . . groundwater (uses) . . .” 1. This Act established the Department of Water Resources (DWR) and gave it the responsibility to regulate water rights and develop long-range water management plans for the State. The Act also established four Active Management Areas (AMAs) in parts of the State in need of immediate groundwater management: the Phoenix, Tucson, Pinal and Prescott Active Management Areas. In these areas, the DWR must prepare long-term water conservation programs, with the help of local Groundwater Users Advisory Councils. Additionally, the Act created a new system of groundwater rights for Active Management Areas, which includes:

1. Grandfathered Rights – a way for persons who have been pumping or using groundwater to preserve their right to continue to use groundwater;
2. Withdrawal Permits – a way for new non-irrigation users of groundwater to obtain the right to withdraw groundwater; and
3. Service Area provisions – a way for cities, towns, private water companies and irrigation districts to continue to serve their customers within their service areas.

This booklet concerns only the first category of rights – GRANDFATHERED RIGHTS. It includes a brief explanation of the three different kinds of grandfathered rights, an application form for each kind of grandfathered right and instructions for filling out the applications. You may be eligible to apply for one or more kind of right; or you may not need to apply at all. Read this explanation carefully before deciding. The deadline for filing applications is September 14, 1981. If you have questions, contact the DWR by mail or by calling the telephone numbers below.

WHAT IS A "GRANDFATHERED RIGHT"?

A grandfathered right is a right to withdraw groundwater which is based on the fact that a person was legally withdrawing and using groundwater prior to the establishment of the Active Management Areas (June 12, 1980). The Groundwater Management Act provides that all existing legal users of groundwater will be allowed to continue to use groundwater, and it provides a means of "quantifying" or determining the amount of these historical rights. There are three kinds of grandfathered rights: IRRIGATION GRANDFATHERED RIGHTS, TYPE 1 NON-IRRIGATION GRANDFATHERED RIGHTS, and TYPE 2 NON-IRRIGATION GRANDFATHERED RIGHTS. An irrigation use is defined in the Act as commercial agricultural irrigation. A non-irrigation use is defined in the Act as any use other than commercial agricultural irrigation.

THE ACT SPECIFIES THAT A PERSON WHO WISHES TO CLAIM A GRANDFATHERED RIGHT BUT WHO FAILS TO FILE AN APPLICATION FOR A RIGHT BY SEPTEMBER 14, 1981, WAIVES AND RELINQUISHES THE RIGHT TO WITHDRAW OR RECEIVE AND USE GROUNDWATER, PURSUANT TO A GRANDFATHERED RIGHT.² However, in deciding whether to file, bear in mind the following:

1. CITIES, TOWNS AND PRIVATE WATER COMPANIES MAY PUMP AS MUCH WATER AS IS NECESSARY TO MEET THE NEEDS OF LANDOWNERS AND RESIDENTS WITHIN THEIR SERVICE AREAS, SUBJECT TO CONSERVATION REQUIREMENTS.³ PERSONS RECEIVING GROUNDWATER FROM CITIES, TOWNS OR PRIVATE WATER COMPANIES FOR NON-IRRIGATION USES DO NOT NEED TO FILE A GRANDFATHERED RIGHT TO BE ENTITLED TO USE THE GROUNDWATER DELIVERED BY THE CITY, TOWN OR PRIVATE WATER COMPANY.
2. PERSONS WITHDRAWING GROUNDWATER ONLY FROM "EXEMPT" WELLS WILL NOT WAIVE OR RELINQUISH THE RIGHT TO WITHDRAW GROUNDWATER BY FAILURE TO FILE FOR A GRANDFATHERED RIGHT.⁴ AN "EXEMPT" WELL IS A WELL WHICH IS USED FOR DOMESTIC PURPOSES, INCLUDING THE NON-COMMERCIAL IRRIGATION OF NOT MORE THAN ONE ACRE OF LAND, AND WHICH HAS A MAXIMUM PUMP CAPACITY OF 35 GALLONS PER MINUTE OR LESS.⁵

After the deadline for filing applications has passed, a registry of all applications will be established and will be open for public inspection at the DWR. There will be a period during which objections to applications may be filed by residents of the Active Management Area. The DWR will review each application, and may consult with the applicant or request additional information from the applicant before making its determination. The DWR may conduct investigations and hold hearings to determine if the information in the application is correct and sufficient to issue a Certificate of Grandfathered Right. The Department will issue Certificates to all persons whose applications meet the requirements for a grandfathered right.

THE IRRIGATION RIGHT

An irrigation grandfathered right is the right to use groundwater to irrigate land for commercial agricultural production.⁶ In the four Active Management Areas only land which was irrigated some time between January 1, 1975, and January 1, 1980, may be irrigated in the future.⁷ Only acres of land which have this history of irrigation are eligible for a grandfathered right.

The maximum amount of groundwater which may be used on the land each year will be determined by the Department according to provisions of the Act, after consultation with farmers, Area Groundwater Users Advisory Councils and technical consultants. The irrigation grandfathered right is owned by the owner of the irrigated land. The State Land Department will be filing applications for all land which it leases for irrigation.

THE TYPE 1 NON-IRRIGATION RIGHT

A Type 1 non-irrigation grandfathered right is based on the fact that land which had been legally irrigated has been retired from irrigation in order to conserve or use groundwater for a specific non-irrigation purpose. A person who has retired legally irrigated land has the right to withdraw from this land up to three acre-feet/acre/year.⁸

A person claiming a Type 1 non-irrigation right must have owned the land since the date it was retired from irrigation, must be able to show evidence that the land was retired for the stated non-irrigation use and must meet other statutory criteria. A person who owns irrigated land may retire that land after the establishment of the Active Management Area (June 12, 1980) and apply for a Type 1 non-irrigation right, but only if the land is outside the exterior boundaries of the service area of any city, town or private water company.⁹

THE TYPE 2 NON-IRRIGATION RIGHT

A Type 2 non-irrigation grandfathered right is based on the user's historical withdrawals rather than on land acreage. The amount of the right is based on the maximum amount withdrawn and used in any one year of the five years preceding June 12, 1980, to the extent that amount exceeds the amount of any Type 1 right claimed.¹⁰ The Type 2 right is owned by the owner of the land from which the groundwater is withdrawn, but the user of the water, if different from the owner of the land, may apply for the right on behalf of the landowner. A person may apply for a Type 2 right for one well or for a group of wells operated conjunctively, that is, in connection with the same distribution system.

FILING FEE

Each application filed must be accompanied by a filing fee of \$20.00. Make checks payable to the Department of Water Resources.

FILING THE APPLICATION

Completed application forms must be mailed to: State of Arizona, Department of Water Resources, P.O. Box 2600, Phoenix, Arizona 85002, and postmarked no later than September 14, 1981.

**GENERAL INSTRUCTIONS
FOR
COMPLETING APPLICATION FORMS**

1. Read "Your Groundwater Rights" and all instructions before filling out any application form.
2. **A PERSON WHO CLAIMS A GRANDFATHERED RIGHT BUT WHO FAILS TO FILE AN APPLICATION FOR A RIGHT BY SEPTEMBER 14, 1981, WAIVES AND RELINQUISHES THE RIGHT TO WITHDRAW OR RECEIVE AND USE GROUNDWATER. (A.R.S. § 45-477)**
3. Applications must be filled in completely.
 - * If an item on the application is not applicable, write NA by the item.
 - * If any information is unobtainable, please indicate and explain.
 - * If a complete answer to an item cannot be given in the space provided on the application form, attach additional 8½ x 11 sheets of paper as needed. Number your answer to correspond to the applicable item on the application and record your name and address on each sheet.
4. Applications must be accompanied by a filing fee of \$20.00. Make checks payable to the Department of Water Resources.
5. **MAIL COMPLETED APPLICATIONS TO:**

**STATE OF ARIZONA
DEPARTMENT OF WATER RESOURCES
P.O. BOX 2600
PHOENIX, ARIZONA 85002**

NO APPLICATIONS WILL BE ACCEPTED IF POSTMARKED AFTER SEPTEMBER 14, 1981.
6. Additional Grandfathered Rights Booklets and individual application forms can be obtained by contacting the Department of Water Resources.

IF YOU HAVE ANY QUESTIONS ON GRANDFATHERED RIGHTS, CALL:

IRRIGATION GRANDFATHERED RIGHT

The following pages are the application forms and instructions for an IRRIGATION GRANDFATHERED RIGHT. Before filling out the application, read each item on the four page application form along with the appropriate comments on the instruction sheet.

For some items, the instruction sheet will tell you of additional information which must be submitted with the application. Be sure to make note of these requirements and include any necessary documents when mailing the completed application. If an application item is not referred to on the instruction sheet, it means that this item is considered to be self-explanatory.

When you have filled out the application form, tear the pages along the perforated line and have the application notarized by a Notary Public. Mail the notarized application, along with any additional sheets of paper and the filing fee, to the Department of Water Resources.

You may file separate application forms for non-contiguous parcels of land. Additional forms are available from the Department. Keep this booklet for instructions.

IRRIGATION GRANDFATHERED RIGHT

INSTRUCTIONS FOR COMPLETING APPLICATION

- ITEM 1.** Type or print the name of the applicant as it appears on land ownership documents. This is the name that will appear on the Certificate of Grandfathered Right.
- ITEM 2.** The legal description must include all land for which a right is being claimed on this application. You may claim a right only for land which you own. You may file separate applications if part of your land is not contiguous. If you are irrigating land which you do not own, the owner of those acres must file an application for those acres. The State Land Department will be filing applications for all land which it leases for irrigation. The legal description should be in the form of the following examples:
- NE $\frac{1}{4}$ NW $\frac{1}{4}$ SECTION 1, TOWNSHIP 12S, RANGE 11E;
PIMA COUNTY, ARIZONA, OR
- SECTIONS 1, 2 AND 3, TOWNSHIP 12S, RANGE 11E;
PIMA COUNTY, ARIZONA
- ITEM 4.** Record the location of each well used to irrigate the land, including wells which you do not own. If your land is served by an irrigation district and it is not served by any wells other than those owned or operated by the district, write NA after Item 4 and do not fill out.
- ITEM 6.** Check Yes if:
- a. you obtain water only from your own well;
 - b. you obtain water only from an irrigation district which owns wells but which has no surface water source;
 - c. you obtain water only from a well owned jointly with other landowners or owned by a neighboring landowner; or
 - d. any combination of the above circumstances.
- Check No if:
- a. you have the right to appropriate surface water;
 - b. you receive water from an irrigation district which has a surface water source in addition to groundwater; or
 - c. you receive water from an irrigation district and you are not sure what the district's source of water is.
- ITEM 8.** The name and address of the previous owner of the land is needed:
- (1) to aid in obtaining information which may not be known by the current owner; and
 - (2) to aid in finding well records which may be filed under the previous owner's name.
- If certain parcels of the land were purchased from different owners since January 1, 1975, give, for each parcel, the legal description, name and address of the previous owner and the date of purchase.
- ITEM 9.** This information is needed to assist in the determination of the maximum amount of water which may be used on the farm. Indicate the method of irrigation which was used for each crop in 1979, for example, flood, sprinkler, furrow, drip, basin or other method. If you need additional space to be specific on cropping patterns and irrigation methods, attach additional sheets of paper.
- ITEM 10.** The amount of groundwater you will be allowed to use by your grandfathered right will be determined on the basis of the amount of water reasonably required to irrigate the crops historically grown, as well as on the basis of the number of acres irrigated in past years. The information from these questions will help us to determine reasonable levels of water use for various crops. Be as accurate as possible. If the amount of groundwater use was measured, indicate the method of measurement and recordation. If estimates are made, attach supporting computations including data, coefficients used, and assumptions. If part of your water supply is recycled return flow or another recycled source and you wish to provide more information about it, do so in the space for comments.
- ITEM 11.** The purpose of this question is to determine which conservation practices are currently in use. "Land levelling" means any method of levelling, including methods other than laser levelling. If you are using a method not listed, you may identify this in the space for comments and indicate the percentage of the farm operation affected.
- ITEM 13.** You may draw the map in any scale sufficient to show the land for which the right is being claimed.

| Last Name | First | Middle or Initial | |
| Mailing Address | City | State | Zip |

NOTE: This form is to be filled out only for acres which you own. If you lease farm land, make sure that the owner of the leased land or his authorized agent is aware of the requirement to file for that land.

2. Legal description of all land presently owned by applicant in the Active Management Area which was legally irrigated at any time between January 1, 1975 and January 1, 1980.

3. Total number of acres in Item 2: _____

4. Describe the location of each well used to irrigate the land. Indicate as accurately as possible the year the well was drilled.

_____ ¼, _____ ¼, _____ ¼, Section _____ Township _____ Range _____ Year _____

_____ ¼, _____ ¼, _____ ¼, Section _____ Township _____ Range _____ Year _____

_____ ¼, _____ ¼, _____ ¼, Section _____ Township _____ Range _____ Year _____

_____ ¼, _____ ¼, _____ ¼, Section _____ Township _____ Range _____ Year _____

5. Is the land served by an irrigation district, agricultural improvement district or irrigation water delivery district? _____ Yes _____ No

If so, give name of district and point of diversion: _____

6. Is groundwater the sole source of water? _____ Yes _____ No

7. If water sources other than groundwater are used, indicate the basis on which those supplies are available to you; for example: court decree, delivery contract, surface water appropriation, contract for sewage effluent, etc. Be as specific as possible.

8. Have you owned the land since January 1, 1975? _____ Yes _____ No. If not, list below the name and address of the previous owner of the land and the date of purchase.

9. Indicate the crops grown, the number of acres planted in each crop and the total number of acres planted in each year. Do not count double cropped acres twice in the last column. Indicate irrigation methods used for each crop for 1979 only.

| | crops grown | # acres in crop | irrigation method | total # acres planted |
|------|-------------|-----------------|-------------------|-----------------------|
| 1979 | | | | |
| 1978 | | | | |
| 1977 | | | | |
| 1976 | | | | |
| 1975 | | | | |

If additional space is needed, attach additional sheet of paper

10. Indicate the amount of water used from each source in each of the five years (acre-feet).

| | 1975 | 1976 | 1977 | 1978 | 1979 |
|-----------------|------|------|------|------|------|
| groundwater | | | | | |
| surface water | | | | | |
| sewage effluent | | | | | |

The above amounts are measured estimated. See instructions for documentation requirements.

TYPE 1 NON-IRRIGATION GRANDFATHERED RIGHT

The following pages are the application form and instructions for a TYPE 1 NON-IRRIGATION GRANDFATHERED RIGHT. Before filling out the application, read each item on the four page application form along with the appropriate comments on the instruction sheet.

For some items, the instruction sheet will tell you of additional information which must be submitted with the application. Be sure to make note of these requirements and include any necessary documents when mailing the completed application. If an application item is not referred to on the instruction sheet, it means that this item is considered to be self-explanatory.

When you have filled out the application form, tear the pages along the perforated line and have the application notarized by a Notary Public. Mail the notarized application, along with any additional sheets of paper and the filing fee, to the Department of Water Resources.

You may file separate application forms for non-contiguous parcels of retired land. Additional forms are available from the Department. Keep this booklet for instructions.

TYPE 1 NON-IRRIGATION GRANDFATHERED RIGHT

INSTRUCTIONS FOR COMPLETING APPLICATION

ITEM 1. Type or print the name of the applicant as it appears on land ownership documents. This is the name that will appear on the Certificate of Grandfathered Right.

ITEM 2. The legal description must include all lands for which a right is being claimed on this application. The legal description should be in the form of the following examples:

NE $\frac{1}{4}$ NW $\frac{1}{4}$ SW $\frac{1}{4}$, SECTION 1, TOWNSHIP 12S, RANGE 11E;
PIMA COUNTY, ARIZONA.

ITEM 4. Record the location of each well which was used to irrigate the land, including wells which you do not own. If your land is served by an irrigation district and it is not served by any wells other than those owned or operated by the district, write NA after Item 4 and do not fill out.

ITEM 6. "Same ownership" is defined in Section 45-461, paragraph 4, Arizona Revised Statutes as:

"ownership by the same person or entity or by successor persons or entities as a result of succession to heirs and personal representatives, corporate and partnership reorganizations, mergers, dissolutions, divestitures, partnerships, partitions, joint ventures, foreclosures, receivership or bankruptcy, purchase of capital stock, sale pursuant to United States Code, title 11, or similar succession, but not by outright sale to a bona fide purchaser for value where no portion of or beneficial interest in the successor interest is retained by the original owner, its shareholders, partners, limited partners or beneficiaries."

Evidence of "same ownership" may include tax statements, a title search or other similar documents.

ITEM 9. A non-irrigation use is any use other than commercial agricultural irrigation.

ITEM 10. Indicate the type of non-irrigation use for which the land was retired, such as residential development or electrical energy generation, and give the name and address of the enterprise if different than that of the applicant.

ITEM 12. Evidence of substantial capital commitments may include partial construction of facilities, non-irrigation improvements of the land and payment for professional services in connection with the non-irrigation use.

ITEM 13. Enclose evidence sufficient to show that:

- (1) The land was retired from irrigation for the purpose of conserving or using water for the non-irrigation use described in this application; and,
- (2) The intention to use or conserve such water for that non-irrigation use existed at the time the land was retired. Evidence of (1) or (2) may include:

- An existing master plan for development of the non-irrigation use;
- A plat map of subdivided or unsubdivided land which has been or will be filed with a city or county or the State Real Estate Department;
- Correspondence or documents indicating an attempt by the owner to have the land zoned or rezoned or to obtain a zoning variance, special exception or amendment to a land use control ordinance which would have the effect of allowing the proposed non-irrigation use;
- A permit for construction of residential, commercial or industrial buildings which are part of or contributory to the non-irrigation use;
- Documents indicating the land was officially reclassified from agricultural use to another land use;
- "Purpose" statement in any existing partnership, joint venture, or corporate documents recorded in the County Recorder's Office which indicates that the non-irrigation use was the purpose of the retirement of the land;
- Dated and signed memoranda, correspondence or opinions indicating that the land in question has been retired for a non-irrigation use;
- Financing arrangements for the proposed non-irrigation use; or
- Other pertinent information.

ITEM 14. You may draw the map in any scale sufficient to show the retired land for which the right is being claimed.

For Department use only

5. On what date did the applicant assume ownership of the land described in Item 2?

_____/_____/_____
DAY MONTH YEAR

6. Has the land been held under the same ownership since it was retired from irrigation? _____ Yes _____ No
If yes, enclose evidence to show same ownership.

7. In what year was the land last irrigated? _____

8. If irrigated in 1980, was the land irrigated after June 12, 1980? Yes No.

9. Was the land retired from irrigation in anticipation of a non-irrigation use? Yes No.

If no, explain why the land was retired. _____

10. If the answer to Item 9 is yes, identify the non-irrigation use for which the land was retired.

11. Was the non-irrigation use described in Item 10 in existence as of June 12, 1980? Yes
 No

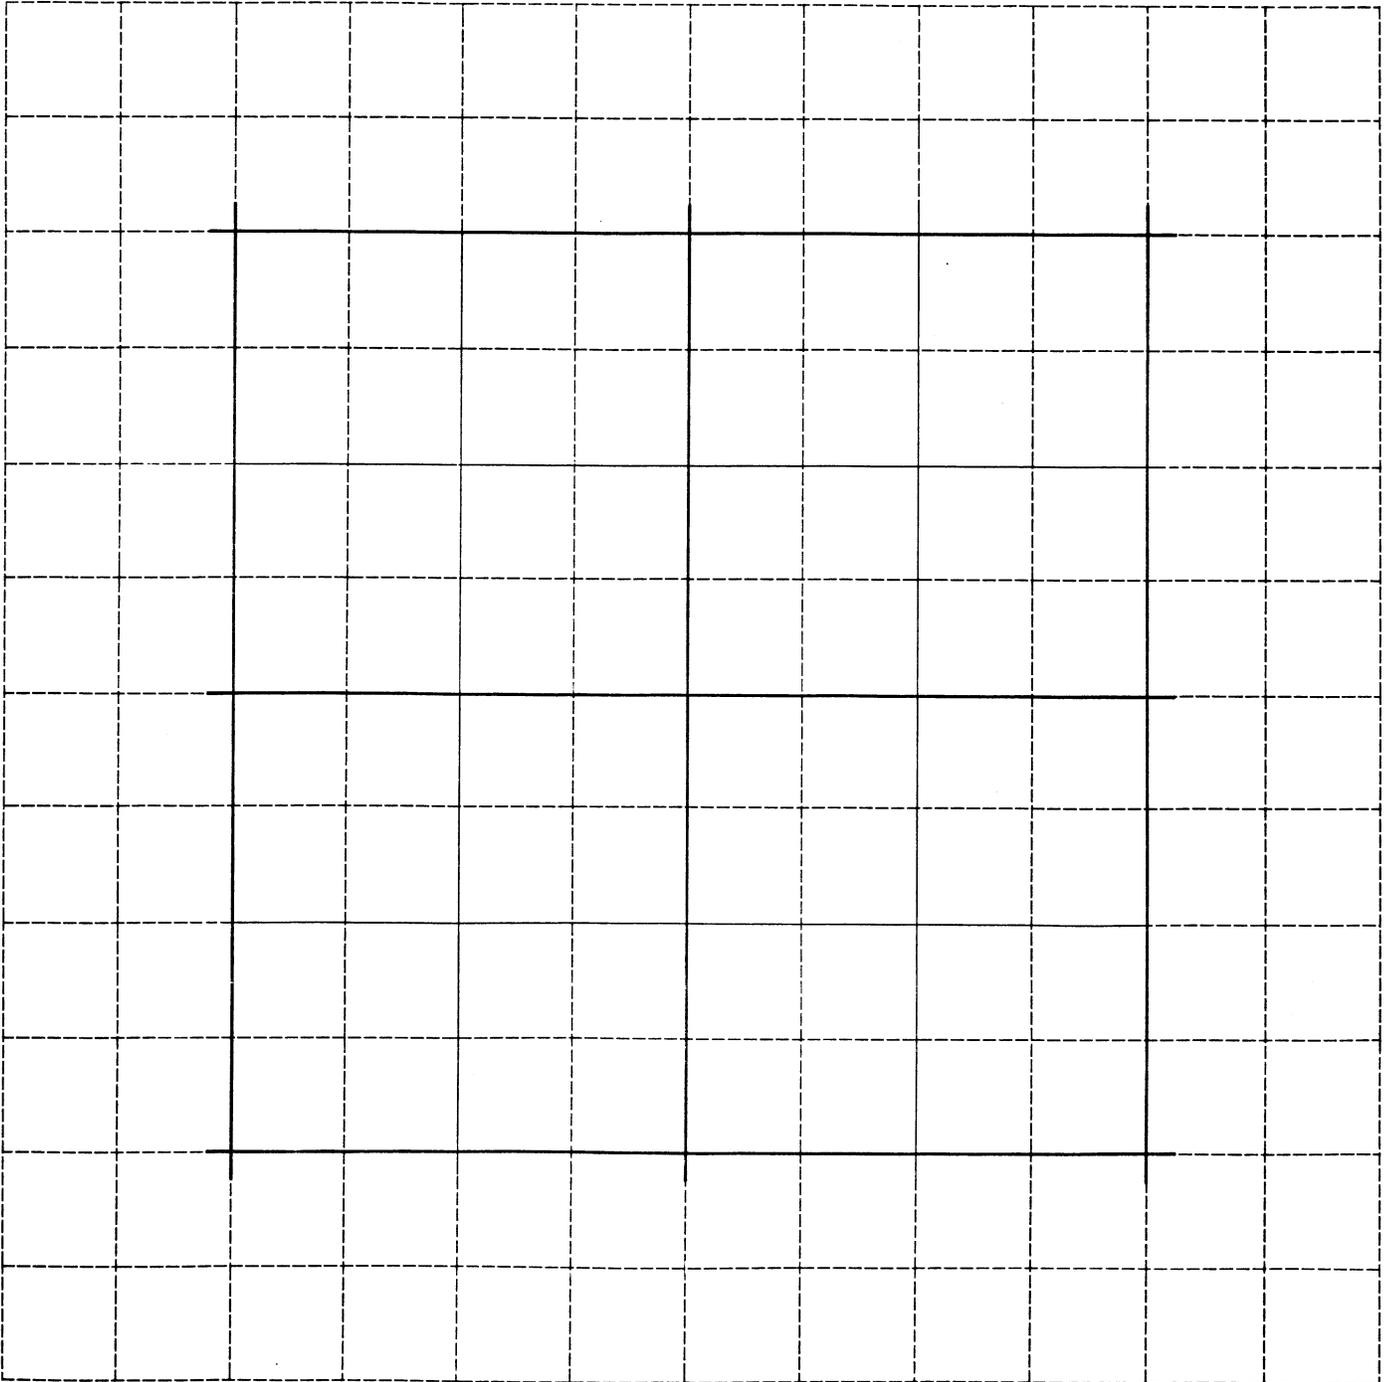

If yes, enclose evidence to show that the use was in existence as of June 12, 1980.

12. If the answer to Item 11 is no, had substantial capital commitments been incurred for the non-irrigation use described in Item 10 as of June 12, 1980? Yes No
If yes, enclose evidence to show substantial capital commitments.

13. If the answers to Items 11 and 12 are no, enclose evidence to show that the land was retired from irrigation for the non-irrigation use described in Item 10.

14. On the grid below, draw a map of the land described in Item 2 and indicate the location of the wells described in Item 4. Indicate the scale of the map in the space below.

TYPE 2 NON-IRRIGATION GRANDFATHERED RIGHT

The following pages are the application form and instructions for a TYPE 2 NON-IRRIGATION GRANDFATHERED RIGHT. Before filling out the application, read each item on the four page application form along with the appropriate comments on the instruction sheet.

For some items, the instruction sheet will tell you of additional information which must be submitted with the application. Be sure to make note of these requirements and include any necessary documents when mailing the completed application. If an application item is not referred to on the instruction sheet, it means that this item is considered to be self-explanatory.

When you have filled out the application form, tear the pages along the perforated line and have the application notarized by a Notary Public. Mail the notarized application, along with any additional sheets of paper and the filing fee, to the Department of Water Resources.

TYPE 2 NON-IRRIGATION GRANDFATHERED RIGHT

INSTRUCTIONS FOR COMPLETING APPLICATION

- ITEM 1.** Type or print the name of the owner of the land from which groundwater is being withdrawn, as it appears on land ownership documents. This is the name that will appear on the Certificate of Grandfathered Right.
- A Type 2 Non-Irrigation Grandfathered Right is owned by the owner of the land from which the water is withdrawn. However, the person using the water, if different from the owner of the land, may file an application on behalf of the owner. If you withdraw water both from wells on land you own and from wells on land you do not own, separate applications must be filed for each category of wells, even if the wells are operated conjunctively. Where separate applications are being filed for this reason and the wells are operated conjunctively, indicate on an attached sheet of paper.
- ITEM 2.** Include the legal description of the land from which all groundwater withdrawals being claimed on this application are made. The legal description should be in the form of the following examples:
- NE $\frac{1}{4}$ NW $\frac{1}{4}$ SW $\frac{1}{4}$, SECTION 1, TOWNSHIP 12S, RANGE 11E;
PIMA COUNTY, ARIZONA, OR
- SECTIONS 1, 2 and 3, TOWNSHIP 12S, RANGE 11E;
PIMA COUNTY, ARIZONA.
- ITEM 3.** If the location for the use of groundwater is the same as that described in Item 2, write SAME.
- ITEM 5.** Indicate the general type of non-irrigation use for which the groundwater is withdrawn, such as a dairy or electrical energy generation, and give the name and address of the enterprise or user, if different from that of the applicant.
- ITEM 6.** The amount of the Type 2 non-irrigation right is based on the maximum amount of groundwater withdrawn and used in any one year of the five years preceding June 12, 1980, to the extent that amount exceeds the amount of any Type 1 right claimed. Choose the 12-month period in which the highest amount of groundwater was withdrawn from the well or wells indicated in Item 4, and set forth the total amount of groundwater withdrawn in that period.
- ITEM 7.** If the amount of groundwater was measured, indicate the method of measurement and recordation. If an estimate is made, attach supporting computations including data, coefficients used and assumptions.
- ITEM 8.** If the applicant owns a facility which was in existence as of June 12, 1980, but was using groundwater for less than one year during the 12-month period prior to June 12, 1980, the amount of the Type 2 right will be an amount determined by the Director to be reasonable to meet the yearly requirements of the facility.
- ITEM 9.** An applicant claiming a Type 1 non-irrigation right and filing an application for a Type 2 non-irrigation right is entitled to a Type 2 right only to the extent that the maximum amount of groundwater withdrawn in any one of the five years exceeds the amount of the Type 1 right being claimed.
- ITEM 10.** If the user of the groundwater being withdrawn is different than the owner of the land, either the user or the owner may file for the Type 2 right on behalf of the owner of the land. However, filing shall not confer any right upon the user. The Type 2 right is owned by the owner of the land.
- ITEM 11.** You may draw the map in any scale sufficient to show the location of the groundwater withdrawals for which the Type 2 right is being claimed.

Registration No. _____
Owner of
Well Site _____
File No. _____

COMPLETION REPORT

1. Completion Report to be filed with the Department within 30 days after installation of pump equipment.
2. The tested pumping capacity of the well in gallons per minute for a non-flowing well should be determined by measuring the discharge of the pump after continuous operation for at least 4 hours and for a flowing well by measuring the natural flow at the land surface.
3. Drawdown of the water level for a non-flowing well should be measured in feet after not less than 4 hours of continuous operation and while still in operation and for a flowing well the shut-in pressure should be measured in feet above the land or in pounds per square inch at the land surface.
4. The static groundwater level should be measured in feet from the land surface immediately prior to the well capacity test.

LOCATION OF THE WELL

Date Well Completed _____ Depth of Well _____

1. Well Test:
Test Pumping Capacity _____ Date Well Tested _____
(Gal. per min.)

Method of Discharge Measurement _____
(weir, orifice, current meter, etc.)

Static Groundwater Level _____ ft. Drawdown _____ ft.
Total Pumping Lift _____ ft. Drawdown _____ lbs.
(Flowing Well)

2. Equipment Installed:

Kind of Pump _____
(turbine, centrifugal, etc.)

Kind of Power _____ H.P. Rating of Motor _____
(Elec., Nat. Gas, Etc.)

I HEREBY CERTIFY that the above statements are true to the best of my knowledge and belief.
